Dataset Information

Dataset Title:

NCCOS Assessment: Community Assessment to Flood Hazard in the United States Virgin Islands,
2023-01-01 to 2024-08-30

Description:

This dataset includes estate level component scores of various indices from the National Centers for Coastal Ocean Science (NCCOS) Community Assessment to Flood Hazard in the United States Virgin Islands (USVI). Indices include social vulnerability, structural vulnerability (and sub-indices), structural exposure (and sub-indices), nearshore environment protection benefits, compounded flood hazard, waterborne toxins and contaminants, vegetation, and potential walkability. Each component score is aggregated to the estate level geography provided by the U.S. Census Bureau. Additionally, intermediary raster-based datasets on stormwater flooding potential, compounded flooding (both near-term-moderate and projected-high), orbital velocity data, a Shannon land use diversity index, and a Visible Atmospherically Resistant Index (VARI) are included.

For full dataset methods please see the NOAA Technical Memorandum NOS NCCOS 334 at <https://repository.library.noaa.gov/view/noaa/66566>.

Purpose:

The U.S. Virgin Islands (USVI) are particularly vulnerable to natural hazards such as erosion, hurricanes, and flooding. These risks are exacerbated by climatic events that contribute to increased storm intensity and extreme weather patterns, including droughts and heavy rainfall. While climate change is a global crisis, its impacts on the USVI are especially severe due to the territory's small size, geographic isolation, and reliance on imported goods. Social determinants of vulnerability—such as economic disparities, limited access to resources, and historical inequities—further compound these challenges. Underserved and historically marginalized communities across the territory often face heightened risks and reduced capacity to prepare for or recover from such hazards. To address these critical issues, the National Centers for Coastal Ocean Science (NCCOS) conducted a place-based, integrated community vulnerability assessment at the estate level to support communities in the USVI.

Project Page:

<https://coastalscience.noaa.gov/project/assessing-community-vulnerability-to-flood-hazard-in-the-u-s-virgin-islands/>

Methods:

This assessment used a geospatial, indicator-driven approach to integrate data from a variety of sources related to community vulnerability in the USVI. These data included measures of social and structural vulnerability and exposure, the nearshore environment, flood hazards, waterborne toxins and contaminants, vegetation, and potential walkability. These indicators were based on territorial needs, existing research, local stakeholder feedback, and data feasibility checks. Each component was analyzed using publicly available data, renormalized using a min-max normalization method, and aggregated to

Data Documentation
NCCOS Community Vulnerability Assessment: VA1 USVI

estate-level geographies. These were then categorized into statistical quantile breaks to show relative rankings across the territory. This integrative approach supports bivariate choropleth mapping for highlighting areas of co-occurrence and prioritization and also highlights estate-level hazard and vulnerability. Additionally, several raster based indices were created in this assessment.

Stormwater flooding potential was calculated using an application of the “FIGUSED” methodology (Kazakis et al., 2015) based on locally relevant datasets. This methodology incorporates seven indicators frequently used to identify areas of high flooding potential, These indicators are: “F” – flow accumulation, “I” – rainfall intensity, “G” – geology (hydrologic soil groups), “U” –land use, “S” – slope, “E” – elevation, and “D” – distance from the drainage network. For each of these indicators, a value of 1 corresponds to higher flood potential, while values closer to zero (or null) correspond to lower flood potential. The final raster dataset ranges from 0-7 and all data were resampled to a 10 meter resolution grid.

Two compounded flooding scenarios were developed in this assessment (1, flood_nm_n.tiff) near-term-moderate compounded flooding (current sea level with additive stormwater flooding potential and Category 3 storm surge) and (2, flood_h_n.tiff) projected-high compounded flooding (additive projected sea level rise, stormwater flooding potential, Category 5 storm surge). Data inputs come from the FIGUSED stormwater potential (figused.tiff), NOAA Office for Coastal Management, and the Category 3 and 5 storm surge models from the NOAA National Hurricane Center. Final values were normalized 0-1 and resamples to a 10 meter resolution grid.

Significant wave height and wave period were obtained from Caribbean Coastal Ocean Observing System (CARICOOS) Simulating Waves Nearshore (SWAN) simulations for 2012–2021 at 0.01° spatial resolution and 3-hr temporal resolution. Model output was averaged by calendar day, then by calendar month, and then across months. The resulting annual mean values were reprojected with linear interpolation to match high-resolution (approximately 10 m) bathymetry grids for St. Thomas/St. John and St Croix. Wavelength was calculated using Hunt’s approximation (Coastal Engineering Research Center, 1985), and representative (i.e., root mean square) orbital bottom velocity was calculated with significant wave height limited to 0.78 x bottom depth (due to wave breaking), following Wiberg and Sherwood (2008). Final values were normalized 0-1 and resamples to a 10 meter resolution grid.

Land use data from the NOAA Coastal Change Analysis Program (NOAA Office for Coastal Management, 2015) were used to calculate a Shannon diversity index as follows: $H = - \sum (p_i * \ln(p_i))$. The final raster dataset was resampled to a 10 meter resolution grid resulting in a final Shannon diversity index with normalized values from 0-1.

Orthographic Imagery from 2020 with sub-meter precision (USVI Hazard Mitigation and Resilience Plan, 2023) were used to calculate a Visible Atmospherically Resistant Index (VARI) equation as follows: $(Green-Red)/(Green+Red-Blue)$. The final raster dataset was normalized 0-1 and resampled to a 10 meter resolution grid resulting in a final vegetation index.

For a full methodological write-up, please see the NOAA Technical Memorandum NOS NCCOS 334 at <https://repository.library.noaa.gov/view/noaa/66566>.
